Abstract

Ornaments express relations between inductive types with the same inductive structure. We implement fully automatic proof reuse for a particular class of ornaments in a Coq plugin, and show how such a tool can give programmers the rewards of using indexed inductive types while automating away many of the costs. The plugin works directly on Coq code; it is the first ornamentation tool for a non-embedded dependently typed language. It is also the first tool to automatically identify ornaments: To lift a function or proof, the user must provide only the source type, the destination type, and the source function or proof. In taking advantage of the mathematical properties of ornaments, our approach produces faster functions and smaller terms than a more general approach to proof reuse in Coq.

Supplement Material The Coq plugin, examples, and case study code for this paper can be found at http://github.com/uwplse/ornamental-search/tree/itp+equiv

1 Introduction

Indexed inductive types make it possible to internalize data into the type level, eliminating the need for certain functions and proofs. Consider, for example, a theorem from the Coq standard library [17] which states that mapping a function over lists preserves length:

\[
map\_length \ T_1 \ T_2 \ (f : T_1 \to T_2) : \forall \ (l : list T), \ length \ (\text{List.map} \ f \ l) = length \ l.
\]

One way to eliminate the need for this theorem is to internalize the length of a list into its type, creating a dependently typed vector (Figure 1). The map function for vectors in Coq’s standard library, for example, carries a proof that it preserves length:

\[
\text{Vector.map} \ \{T_1\} \ \{T_2\} \ (f : T_1 \to T_2) : \forall \ (n : \text{nat}) \ (v : \text{vector} T_1 n), \ \text{vector} T_2 n.
\]

so that a theorem like map\_length is no longer necessary.

Unfortunately, for all of the benefits they bring, indexed inductive types are notoriously difficult to use. Dependently typed vectors, for example, impose proof obligations about their lengths on the user; these can quickly spiral out of control. In recent coq-club threads asking for advice on how to use dependently typed vectors, experts called them “not suitable for extended use” [7] and noted that “almost no one should be using [them] for anything” [8].
list (T : Type) : Type := vector (T : Type) : nat → Type :=
| nil : list T | nilV : vector T 0
| cons : T → list T → list T. | consV :
T → list T → list T. ∀ (n : nat), T → vector T n → vector T (S n).

Figure 1 A vector (right) is a list (left) indexed by its length (highlighted in orange).

We show how proof reuse—reusing existing proofs to derive new proofs—can tackle many of the challenges posed by indexed inductive types, allowing the user to move between unindexed and indexed versions of a type (for example, lists and vectors) and reap the benefits of indexed types without many of the costs. We focus in particular on the benefits of this approach in deriving functions and proofs for fully-determined indexed types, when the index is a fold over the unindexed version (such as the length of a list). In our approach, the user writes functions and proofs over the unindexed version, and a tool then automatically lifts those functions and proofs to the indexed version. The user can then switch back to working with the unindexed version by running the tool in the opposite direction. In that way, the user can use lists when lists are convenient, and vectors when vectors are convenient.

Our approach uses ornaments [23], which express relations between types that preserve inductive structure, and which enable lifting of functions and proofs along those relations. Recent work introduced ornaments to a subset of ML and was heavily focused on automatically lifting functions [33]; until now, such an approach was not available in a dependently typed language. Existing implementations of ornaments in dependently typed languages work only in embedded languages, and have little to no automation [20, 23, 11].

Our main contribution is a Coq plugin for automatic function and proof reuse using ornaments. Our plugin DEVOID (Dependent Equivalences Via Ornamenting Inductive Definitions) works directly on Coq code, rather than on an embedded language. DEVOID automates lifting functions and proofs along algebraic ornaments [23], a particular class of ornaments that represent fully-determined indexed types like lists and vectors. DEVOID implements an algorithm to search for ornaments between these types—to the best of our knowledge, the first search algorithm for ornaments—and an algorithm to lift functions and proofs along the ornaments it discovers.

We motivate (Section 2), specify (Section 3), and formalize (Section 4) the search and lifting algorithms that DEVOID implements (Section 5). A comparison to a more general proof reuse approach (Section 6) demonstrates the benefits of using ornaments: DEVOID imposes less of a proof burden on the user, and produces smaller terms and faster functions.

2 Motivating Example: Porting a Library

DEVOID is a plugin for Coq 8.8; it can be found in the repository linked to as Supplement Material under the abstract of this paper. To see how it works, consider an example using the types from Figure 1, the code for which is in Example.v. In this example, we lift two list zip functions and a proof of a theorem relating them from the Haskell CoreSpec library [29]:

zip {T1, T2} : list T1 → list T2 → list (T1 * T2).

zip_with {T1, T2, T3} (f : T1 → T2 → T3) : list T1 → list T2 → list T3.

zip_with_is_zip {T1, T2} : ∀(l1:list T1)(l2:list T2), zip_with pair l1 l2 = zip l1 l2.

DEVOID runs a preprocessing step before lifting, which we describe in Section 5; we assume this step has already run. We use the cyan background color to denote tool-produced terms.
and the names that refer to them. We run DEVOID to lift functions and proofs from lists to vectors, but it can also lift in the opposite direction.

**Step 1: Search.** We first use DEVOID’s **Find ornament** command to search for the relation between lists and vectors:

```
Find ornament list vector.
```

This produces functions which together form an equivalence (denoted \(\simeq\)):

```
list T \simeq \Sigma (n : nat).vector T n
```

**Step 2: Lift.** We then lift our functions and proofs along that equivalence using DEVOID’s **Lift** command. For example, to lift `zip`, we run the command:

```
Lift list vector in zip as zipV_p.
```

This produces a function with this type:

```
zipV_p \{T_1 T_2\} : \Sigma n. vector T_1 n \to \Sigma n. vector T_2 n \to \Sigma n. vector (T_1 * T_2) n.
```

that behaves like `zip`, but whose body no longer refers to lists. We lift our proof similarly:

```
Lift list vector in zip_with_is_zip as zip_with_is_zipV_p.
```

This produces a proof of the analogous result (denoting projections by \(\pi_l\) and \(\pi_r\)):

```
zip_with_is_zipV_p \{T_1 T_2\} : \forall \bar{v} (v_1 : vector T_1 n_1) (v_2 : vector T_2 n_2),
zip_withV_p \bar{v} (\exists (\pi_l v_1) (\pi_r v_1)) (\exists (\pi_l v_2) (\pi_r v_2)) =
zipV_p (\exists (\pi_l v_1) (\pi_r v_1)) (\exists (\pi_l v_2) (\pi_r v_2)).
```

that no longer refers to lists, `zip`, or `zip_with` in any way.

**Step 3: Unpack.** The lifted terms operate over vectors whose lengths are **packed** inside of a sigma type. While this lets **Lift** provide strong theoretical guarantees, it can make it difficult to interface with the lifted code. We can recover **unpacked** terms using DEVOID’s **Unpack** command. For example, to unpack `zipV_p`, we run the command:

```
Unpack zipV_p as zipV.
```

This produces functions and proofs that operate directly over vectors, like `zipV`:

```
zip \{T_1 T_2\} \{n_1\} (v_1 : vector T_1 n_1) \{n_2\} (v_2 : vector T_2 n_2) :
vector (T_1 * T_2) (\pi_l (zipV_p (\exists n_1 v_1) (\exists n_2 v_2))).
```

and `zip_with_is_zipV`:

```
zip_with_is_zipV : \forall \{T_1 T_2\} \{n_1\} (v_1 : vector T_1 n_1) \{n_2\} (v_2 : vector T_2 n_2),
eq_dep _ _ _ (zip_withV_p \bar{v} v_1 v_2) _ (zipV v_1 v_2).
```

**Step 4: Interface.** For any two inputs of the same length, `zipV` and `zipV_with` contain proofs that the output has the same length as the inputs. However, the types obscure this information. **Example.v** explains how to recover more user-friendly types, like that of `zipV_uf`:

```
zipV_uf \{T_1 T_2\} \{n\} : vector T_1 n \to vector T_2 n \to vector (T_1 * T_2) n.
```

and that of `zip_withV_uf`:
which both restrict input lengths. We can then use our lifted functions and proofs in client code. For example, we can write a different version of Coq’s \texttt{BVand} function for bitvectors:

\begin{verbatim}
BVand (n) (v_1 : vector bool n) (v_2 : vector bool n) : vector bool n :=
  zip_withV_uf andb v_1 v_2.
\end{verbatim}

By working over lists, we are able to reason about only the interesting pieces, thinking about indices only when relevant; in contrast, when writing proofs over vectors, even simple theorems can generate tricky proof obligations. With DEVOID, the programmer can use the lifted functions and proofs to interface with code that uses vectors, then switch back to lists when vectors are unmanageable. In essence, ornaments form the glue between these types.

3 Specification

This section specifies the two commands that DEVOID implements:

1. \textbf{Find ornament} searches for ornaments (specified in Section 3.1, described in Section 4.1).
2. \textbf{Lift} lifts along those ornaments (specified in Section 3.2, described in Section 4.2).

\textbf{Algebraic Ornaments.} DEVOID searches for and lifts along algebraic ornaments in particular. An algebraic ornament relates an inductive type \( A \) to an indexed version of that type \( B \) with a new index of type \( I_B \), where the new index is fully determined by a unique fold over \( A \). For example, vector is exactly list with a new index of type \( \text{nat} \), where the new index is fully determined by the \texttt{length} function. Consequentially, there are two functions:

\begin{verbatim}
ltv : list T → Σ(n : nat).vector T n.
vtl : Σ(n : nat).vector T n → list T.
\end{verbatim}

that are mutual inverses:

\begin{verbatim}
∀ (l : list T), vtl (ltv l) = l.
∀ (v : Σ(n : nat).vector T n), ltv (vtl v) = v.
\end{verbatim}

and therefore form the type equivalence from Section 2. Moreover, since the new index is fully determined by \texttt{length}, we can relate \texttt{length} to \texttt{ltv}:

\begin{verbatim}
∀ (l : list T), length l = π_1 (ltv l).
\end{verbatim}

In general, we can view an algebraic ornament as a type equivalence:

\[ A \overset{\tilde{\gamma}}{\rightsquigarrow} \Sigma(n : I_B) B (\text{index } n \tilde{\gamma}) \]

where \( \tilde{\gamma} \) are the indices of \( A \), \( I_B \) is a function over those indices, and the \texttt{index} operation inserts the new index \( n \) at the right offset. Such a type equivalence consists of two functions [32]:

\begin{verbatim}
promote : A \tilde{\gamma} → Σ(n : I_B) B (\text{index } n \tilde{\gamma}).
forget : Σ(n : I_B) B (\text{index } n \tilde{\gamma}) → A \tilde{\gamma}.
\end{verbatim}

that are mutual inverses:

\[1\] The adjunction condition follows from section and retraction.
An algebraic ornament is additionally equipped with an indexer, which is a unique fold:

\[ \text{indexer} : A \vec{i} \rightarrow I_B \vec{i} , \]

which projects the promoted index:

\[ \text{coherence} : \forall (a : A \vec{i}), \text{indexer } a = \pi_l (\text{promote } a). \]

Following existing work [20], we call this equivalence the \emph{ornamental promotion isomorphism}; when it holds and the indexer exists, we say that \( B \) is an algebraic ornament of \( A \).

\textbf{Find ornament} searches for algebraic ornaments between types and is, to the best of our knowledge, the first search algorithm for ornaments. \textbf{Lift} then lifts functions and proofs along those ornaments, removing all references to the old type. Both commands make some additional assumptions for simplicity; detailed explanations for these are in \texttt{Assumptions.v}.

### 3.1 Find ornament

In their original form, ornaments are a programming mechanism: Given a type \( A \), an ornament determines some new type \( B \). We invert this process for algebraic ornaments: Given types \( A \) and \( B \), \texttt{DEVVOID} searches for an ornament between them. This is possible for algebraic ornaments precisely because the indexer is extensionally unique. For example, all possible indexers for \texttt{list} and \texttt{vector} must compute the length of a list; if we were to try doubling the length instead, we would not be able to satisfy the equivalence.

\textbf{Find ornament} takes two inductive types and searches for the components of the ornamental promotion isomorphism between them:

- **Inputs**: Inductive types \( A \) and \( B \), assuming:
  - \( B \) is an algebraic ornament of \( A \),
  - \( B \) has the same number of constructors in the same order as \( A \),
  - \( A \) and \( B \) do not contain recursive references to themselves under products, and
  - for every recursive reference to \( A \) in \( A \), there is exactly one new hypothesis in \( B \), which is exactly the new index of the corresponding recursive reference in \( B \).
- **Outputs**: Functions \texttt{promote}, \texttt{forget}, and \texttt{indexer}, guaranteeing:
  - the outputs form the ornamental promotion isomorphism between the inputs.

\textbf{Find ornament} includes an option to generate a proof that the outputs form the ornamental promotion isomorphism; by default, this option is false, since \textbf{Lift} does not need this proof.

### 3.2 Lift

\textbf{Lift} lifts a term along the ornamental promotion isomorphism between \( A \) and \( B \). That is, it lifts types to corresponding types and terms of those types to corresponding terms:

\begin{align*}
\text{Lift list vector in list as vector.p.} & \quad (\ast \text{ vector.p } T := \Sigma (n : \text{nat}).\text{vector } T \text{ n } \ast) \\
\text{Lift list vector in (cons 5 nil) as v.p.} & \quad (\ast \text{ v.p } := \exists (\text{consV 0 5 nilV } \ast) \\
\end{align*}

Furthermore, it recursively preserves this equivalence, lifting non-dependent functions like \texttt{zip} so that they map equivalent inputs to equivalent outputs:

\[ \forall (T_1, T_2) \ l_1 \ l_2, \text{ promote (zip } l_1 \ l_2) = \text{ zipV_p (promote } l_1) \ (\text{promote } l_2). \]
This intuition breaks down with dependent types. With equivalence alone, we can’t state the relationship between `zip_with_is_zip` and `zip_with_is_zipV_p`, since the unlifted conclusion:

```
zip_with pair l₁ l₂ = zip l₁ l₂.
```

does not have the same type as the conclusion of the lifted version applied to promoted arguments; any relation between these terms must be heterogeneous.

In particular, **Lift** preserves the univalent parametric relation [30], a heterogenous parametric relation that strengthens an existing parametric relation for dependent types [2] to make it possible to state preservation of an equivalence: Two terms \( t \) and \( t' \) are related by the univalent parametric relation \( [[Γ]]_u ⊢ [t]_u : [[T]]_u \ t' \) at type \( T \) in environment \( Γ \) if they are equivalent up to transport. The details of this relation can be found in the cited work.

**Lift** preserves this relation using the components that **Find ornament** discovers, and additionally guarantees that the lifted term does not refer to the old type in any way:

- **Inputs:** The inputs to and outputs from **Find ornament**, along with a term \( t \), assuming:
  - the assumptions and guarantees from **Find ornament** hold,
  - \( I_B \) is not \( A \),
  - \( t \) is well-typed and fully \( η \)-expanded,
  - \( t \) does not apply **promote** or **forget**, and
  - \( t \) does not reference \( B \).

- **Outputs:** A term \( t' \), guaranteeing:
  - if \( t \) is \( A \vec{i} \), then \( t' \) is \( Σ(n : I_B) \vec{i}).B(\text{index } n \vec{i}) \),
  - \( t' \) does not reference \( A \), and
  - if in the current environment \( Γ ⊢ t : T \), then \( [[Γ]]_u ⊢ [t]_u : [[T]]_u \ t' \).

**Lift** does not require a proof that the input components form the ornamental promotion isomorphism, but they must for the guarantees to hold. It can operate in either direction, promoting from \( A \) to packed \( B \) or forgetting in the opposite direction; the specification for the forgetful direction is similar, with extra restrictions on how \( B \) is used within \( t \).

## 4 Algorithms

This section describes the algorithms that implement the specifications from Section 3.

**Presentation.** We present both algorithms relationally, using a set of judgments; to turn these relations into algorithms, prioritize the rules by running the derivations in order, falling back to the original term when no rules match. The default rule for a list of terms is to run the derivation on each element of the list individually.

**Notes on Syntax.** The language the algorithms operate over is CIC\(ω\) with primitive eliminators; this is a simplified version of the type theory underlying Coq. Figure 2 contains the syntax (which includes variables, sorts, product types, functions, inductive types, constructors, and eliminators), as well as the syntax for some judgments and operations, the rules for which are standard and thus omitted. For simplicity of presentation, we assume variables are names; we assume that all names are fresh. As in Coq, we assume the existence of an inductive type \( Σ \) for sigma types with projections \( π_l \) and \( π_r \); for simplicity, we assume projections are primitive. Throughout, we use \( \vec{i} \) and \( \{t₁, \ldots, t_n\} \) to denote lists of terms, and we use \( \vec{i}[j] \) to denote accessing the element of the list \( \vec{i} \) at offset \( j \).
\( \langle i \rangle \in \mathbb{N}, \langle s \rangle \in \text{Vars}, \langle a \rangle \in \{ \text{Prop}, \text{Set}, \text{Type}(i) \} \)

\( \langle t \rangle := \langle v \rangle | \langle s \rangle | \Pi(\langle w \rangle : \langle t \rangle) . \langle t \rangle | \lambda(\langle v \rangle : \langle t \rangle) . \langle t \rangle | \langle t \rangle \langle t \rangle | \text{Ind}(\langle t \rangle) \langle t \rangle | \text{Constr}(\langle i \rangle \langle t \rangle) | \text{Elim}(\langle i \rangle \langle t \rangle) \langle t \rangle \langle t \rangle \}

\( \Gamma \vdash t : T \) // type checking
\( \Gamma \vdash t_1 \equiv_{\text{def}} t_2 \) // definitional equality
\( t_2 \) // beta-reduction
\( t_{\beta\delta\eta} \) // normalization
\( t[y/x] \) // substitution
\( \xi(I, Q, c, C) \) // type of eliminator

\[ \begin{align*}
A := & \ \text{Ind}(T_Y : \Pi(i_A : \bar{X}_A).s_A)\{C_{A_1}, \ldots, C_{A_n}\} \\
B := & \ \text{Ind}(T_B : \Pi(i_B : \bar{X}_B).s_B)\{C_{B_1}, \ldots, C_{B_n}\} \\
\forall 1 \leq i \leq n, & \\
E_{A_i}(p_A : P_A) := & \ \xi(A, p_A, \text{Constr}(i, A), C_{A_i}) \\
E_{B_i}(p_B : P_B) := & \ \xi(B, p_B, \text{Constr}(i, B), C_{B_i})
\end{align*} \]

\[ \begin{align*}
P_A := & \ \Pi(i_A \bar{X}_A)(a : A i_A).s_A \\
P_B := & \ \Pi(i_B \bar{X}_B)(b : B i_B).s_B \\
\text{index} := & \ \text{insert (off } A B) \\
\text{deindex} := & \ \text{remove (off } A B)
\end{align*} \]

\[ \begin{align*}
\text{Figure 2} & \text{ CIC}_2 \text{ syntax (left, from existing work [31]) and judgments and operations (right).}
\end{align*} \]

\[ \begin{align*}
\text{Common Definitions.} & \text{ The algorithms assume list insertion and removal functions insert and remove, plus two functions DEVOID implements: off computes the offset of the new index of type } I_B \text{ in } B \text{'s indices, and new determines whether a hypothesis in a case of the eliminator type of } B \text{ is new. Figure 3 contains other common definitions, the names for which are reserved: The index and deindex functions insert an index into and remove an index from a list at the index computed by off. Input type } A \text{ expands to an inductive type with indices of types } X_A, \text{ sort } s_A, \text{ and constructors } \{C_{A_1}, \ldots, C_{A_n}\}. P_A \text{ denotes the type of the motive of the eliminator of } A, \text{ and each } E_{A_i} \text{ denotes the type of the eliminator for the } i \text{th constructor of } A. \text{ Analogous names are also reserved for input type } B.
\end{align*} \]

4.1 Find ornament

The Find ornament algorithm implements the specification from Section 3.1. It builds on three intermediate steps: one to generate each of indexer, promote, and forget. Figure 4 shows the algorithm for generating indexer. The algorithms for generating promote and forget are similar; Figure 5 shows only the derivations for generating promote that are different from those for generating indexer, and the derivations for generating forget are omitted.

4.1.1 Searching for the Indexer

Search generates the indexer by traversing the types of the eliminators for \( A \) and \( B \) in parallel using the algorithm from Figure 4, which consists of three judgments: one to generate the motive, one to generate each case, and one to compose the motive and cases.

Generating the Motive. The \( (T_A, T_B) \ \mathcal{G}_{ia} \ t \) judgment consists of only the derivation INDEX-MOTIVE, which computes the indexer motive from the types \( A \) and \( B \) (expanded in Figure 3). It does this by constructing a function with \( A \) and its indices as premises, and the type \( I_B \) in the conclusion with the appropriate indices. Consider list and vector:

\[ \text{list } T := \text{Ind} \ (T_Y : \text{Type}) \{\ldots\} \quad \text{vector } T := \text{Ind} \ (T_B : \Pi(n : \text{nat}).\text{Type}) \{\ldots\} \]

For these types, INDEX-MOTIVE computes the motive:

\[ \lambda (1 : \text{list } T). \text{ .nat} \]
Finally, the environment with recurses into both bodies, substituting the new inductive hypothesis for the index in the then takes over. It substitutes the new motive in the inductive hypothesis, then is next. It recurses into product types when the hypothesis is neither a Index-Prod exists. For example, in the inductive case of to the environment, then recurses into the body of only the type for which the index already Index-Conclusion computes the conclusion by taking the index of motive

Figure 4 Identifying the indexer function.

Generating Each Case. The $\Gamma \vdash (T_A, T_B) \psi_{i_m}$ judgment generates each case of the indexer by traversing in parallel the corresponding cases of the eliminator types for $A$ and $B$. It consists of four derivations: Index-Conclusion handles base cases and conclusions of inductive cases, while Index-Hypothesis, Index-Ind, and Index-Prod recurse into products.

Index-Hypothesis handles each new hypothesis that corresponds to a new index in an inductive hypothesis of an inductive case of the eliminator type for $T$. It adds the new index to the environment, then recurses into the body of only the type for which the index already exists. For example, in the inductive case of $\text{list}$ and $\text{vector}$, $\text{new}$ determines that $n$ is the new hypothesis. Index-Hypothesis then recurses into the body of only the index case:

\[
\Pi \ (t_i : \mathcal{T}) \ (\Pi_i : pA \ l), \ldots \ \Pi \ (t_i : \mathcal{T}) \ (v : \text{vector } T n) \ (\Pi_i : pB n v), \ldots
\]

Index-Prod is next. It recurses into product types when the hypothesis is neither a new index nor an inductive hypothesis. Here, it runs twice, recursing into the body and substituting names until it hits the inductive hypothesis for both types:

\[
\Pi \ (\Pi_i : pA l), \ pA \ (\text{cons } t_1 l) \ \Pi \ (\Pi_i : pB n l), \ pB \ (S n) \ (\text{cons } V n t_1 l)
\]

Index-Ind then takes over. It substitutes the new motive in the inductive hypothesis, then recurses into both bodies, substituting the new inductive hypothesis for the index in the eliminator type for $B$. Here, it substitutes the new motive for $pA$ in the type of $\Pi_i$, extends the environment with $\Pi_i$, then substitutes $\Pi_i$ for $n$, so that it recurses on these types:

\[
pA \ (\text{cons } t_1 l) \ \ pB \ (S \ \Pi_i) \ (\text{cons } V \ \Pi_i \ t_1 l)
\]

Finally, Index-Conclusion computes the conclusion by taking the index of motive $pB$ at off $A B$, here $S \ \Pi_i$. In total, this produces a function that computes the length of $\text{cons } t l$:
The presented page of a document contains mathematical notation and text explaining the core search algorithm. A snippet of the text is shown below:

\[
\begin{align*}
\text{Promote-Motive} & \quad \Gamma \vdash (A, B) \psi_\pi t \\
\Gamma & \vdash (A, B) \psi_{pm} \lambda(i_a : X_A)(a : A i_a).B \ (\text{index } (\pi i_a a) i_a) \\
\text{Promote-Conclusion} & \quad \Gamma \vdash (A, B) \psi_{pm} t \\
\Gamma & \vdash (A, B) \psi_{pm} p \\
\Gamma & \vdash (A, B) \psi_{pm} t \\
\Gamma & \vdash (A, B) \psi_{pm} \lambda(i_A : X_A)(a : A i_A).\exists (\pi i_A a) (\text{Elim}(a, p) f)
\end{align*}
\]

**Figure 5** Identifying the promotion function.

**Composing the Result.** The \( \Gamma \vdash (T_A, T_B) \psi_t t \) judgment consists of only INDEX-IND, which identifies the motive and each case using the other two judgments, then composes the result. In the case of list and vector, this produces a function that computes the length of a list:

\[
\lambda (l : \text{list } T).\text{Elim}(l, \lambda (l : \text{list } T). \text{nat}) \\
\{0, \lambda (t : T) (l : \text{list } T) (\text{IH}\_l : (\lambda (l : \text{list } T). \text{nat}) l).S \text{IH}\_l\}
\]

**4.1.2 Searching for Promote and Forget**

Figure 5 shows the interesting derivations for the judgment \( (T_A, T_B) \psi_t t \) that searches for `promote`. **Promote-Motive** identifies the motive as \( B \) with a new index (which it computes using `indexer`, denoted by metavariable \( \pi \)). When **Promote-III** recurses, it substitutes the inductive hypothesis for the term rather than for its index, and it substitutes the new index (which it also computes using `indexer`) inside of that term. **Promote-Conclusion** returns the entire term, rather than its index. Finally, **Promote-Ind** not only recurses into each case, but also packs the result. The omitted derivations to search for `forget` are similar, except that the domain and range are switched. Consequently, `indexer` is never needed; **Forget-Motive** removes the index rather than inserting it, and **Forget-III** no longer substitutes the index. Additionally, **Forget-Hypothesis** adds the hypothesis for the new index rather than skipping it, and **Forget-Ind** eliminates over the projection rather than packing the result.

**4.1.3 Core Search Algorithm**

The core search algorithm produces `indexer`, `promote`, and `forget`, then composes them into a tuple. This tuple is how `DEVOID` represents ornaments internally. `DEVOID` includes an option to generate a proof that these components form the ornamental promotion isomorphism; by default, this is disabled, since `Lift` does not need this proof. The implementation of this option gives intuition for correctness of the search algorithm, and is described in Section 5.3.
The Lift

4.2 Lifting Eliminators

The Lift algorithm implements the specification from Section 3.2. We show only one direction of the algorithm, promoting from $A$ to packed $B$; the forgetful direction is similar. The core algorithm (Figure 9) builds on a set of common definitions (Figure 6) and two intermediate judgments: one to lift eliminators (Figure 7) and one to lift constructors (Figure 8).

Common Definitions. The common definitions (Figure 6) define some useful syntax: $\uparrow$ applies promote, $\downarrow$ applies forget, and $\iota_{i_B}$ applies indexer. $\iota_{i_B}$ packs a term of type $B$ into an existential with the index at the appropriate offset. $\uparrow_B$ and $\iota_B$ promote and then project; $\downarrow_A$ packs and forgets, and $\downarrow_{i_B}$ packs, forgets, and then applies indexer to project the index.

4.2.1 Lifting Eliminators

The $\Gamma \vdash t \uparrow E t'$ judgment (Figure 7) defines rules for lifting the motive and case of an eliminator, changing the domain of induction from $A$ to $B$. The intuition is that any term of type $A$ is the result of forgetting some term of type packed $B$. Then, since $A$ and $B$ have the same inductive structure, we can lift the eliminator of $A$ to the eliminator of $B$, and move that forgetfulness inside of each case. For example, the following terms are propositionally equal:

$$\text{Elim}(\lambda A. b) \cdot p_A \{\} \quad \text{Elim}(b, \lambda(n:nat)(v:vector T n).p_A (\downarrow A \ v)) \{\}$$

$$\text{Elim}(\lambda(t_i:T)(l:list T)(iH_i:p_A \ 1). \ \ i_{\text{cons}} t_i \ 1 \ \ iH_i) \quad \text{Elim}(\lambda(n:nat)(v:vector T n)(iH_n:p_A (\downarrow A \ v)). \ \ i_{\text{cons}} v \ (\downarrow A \ v) \ \ iH_n)$$

\begin{align*}
\text{DROP-INDEX} & \quad \text{FORGET-ARG} \\
\text{new } n b & \quad \Gamma, \ n : t \vdash (f, \ n) \uparrow E x \ b' \\
\Gamma \vdash (f, \ ll(n : t) b) \uparrow E x \ \lambda(n : t) b' & \quad \Gamma, \ n : B \ i \vdash ((f (\downarrow A \ n)) b, \ n) \uparrow E x \ b' \\
\text{ARG} & \quad \text{CONCL} \\
\Gamma \vdash (f, \ ll(n : t, b) \uparrow E x \ \lambda(n : t) b') & \quad \Gamma \vdash (t, \ \Pi(n : B \ i) b) \uparrow E x \ \lambda(n : B \ i) b' \\
\text{MOTIVE} & \quad \text{CASE} \\
\Gamma \vdash p_A : P_A & \quad \Gamma \vdash p_A \uparrow E p_B \\
\Gamma \vdash p_A \uparrow E \lambda(i : X_B)(b : B \ i). (p_A \ (\text{deindex } i) (\downarrow A \ b) b) & \quad \Gamma \vdash f_i : E_A, p_A \\
\Gamma \vdash f_i \uparrow E f'_b & \quad \Gamma \vdash (f_i, \ E_B, p_B) \uparrow E x f'_b \\
\end{align*}
4.2.2 Lifting Constructors

The induction rules implement this transformation. \textsc{Case} lifts a case of the eliminator by first recursively lifting the motive, then using the lifted motive to compute the type of the new case, and then using that type to compute the body of the new case. In the example above, when lifting the inductive case, it first recursively lifts the motive \( p_A \) using \textsc{Motive}, which drops the index, packs and forgets the argument of type \( B \), and then \( \beta \)-reduces the result, eliminating references to \( B \). This produces the new motive:

\[
\lambda (n: \text{nat})(v: \text{vector } T n). p_A (\downarrow_A v)
\]

which \textsc{Case} then uses to compute the type of the inductive case of the eliminator for \( B \):

\[
\Pi (t_v: T)(n: \text{nat})(\text{IH}_v: p_A (\downarrow_A v)). (\downarrow_A (\text{consV } t_v (S n) v))
\]

The \( \vdash (t, T) \uparrow_{E_x} t' \) judgment then uses that type to compute the lifted function body. It computes this in a similar way to \textsc{Motive}, except that there are as many indices to drop and arguments to pack and forget as there are inductive hypotheses, and these do not occur in predictable places, so more rules are involved. This computes the new function:

\[
\lambda (n: \text{nat})(t_v: T)(v: \text{vector } T n)(\text{IH}_v: p_A (\downarrow_A v)). f_{\text{cons}} t_v (\downarrow_A v) \text{ IH}_v
\]

This derivation consists of only one rule: \textsc{Normalize}, which normalizes the promotion of the constructor. This is guaranteed to succeed because the application of the constructor is fully \( \eta \)-expanded. The core algorithm later internalizes the promotion functions in the result.

4.2.3 Core Lifting Algorithm

The core algorithm (Figure 9) builds on these intermediate judgments. The interesting derivations for correctness are the first six: \textsc{Lift-Elim} and \textsc{Lift-Constr} use the judgments for lifting eliminators and constructors of \( A \). \textsc{Internalize} internalizes the explicit promote functions from the lifted constructors to recursive applications of the algorithm. \textsc{Retraction} and \textsc{Coherence} use the respective properties of the ornamental promotion isomorphism metatheoretically: the first to drop the explicit forget functions from the lifted eliminators, and the second to lift the indexer to a projection (in the forgetful direction, \textsc{Section} replaces \textsc{Retraction}). Finally, \textsc{Equivalence} lifts \( A \) along the equivalence to packed \( B \). The remaining derivations recurse predictably.
This section describes a sample of these changes from each of three categories: addressing differences between Coq and the type theory that the algorithms assume (Section 5.1), optimizing for efficiency (Section 5.2), and improving usability (Section 5.3).

5 Implementation

The DEVOID Coq plugin implements the algorithms from Section 4; the link to the code is in Supplement Material. DEVOID cannot produce an ill-typed term, since Coq type checks all terms that plugins produce and rejects ill-typed terms. The implementations of Find ornament (search.ml) and Lift (lift.ml) are mostly the same as the algorithms, but with changes to address implementation challenges that scale the algorithms to a Coq tool for proof engineers. This section describes a sample of these changes from each of three categories: addressing differences between Coq and the type theory that the algorithms assume (Section 5.1), optimizing for efficiency (Section 5.2), and improving usability (Section 5.3).

5.1 Addressing Language Differences

Fixpoints. Coq implements eliminators in terms of pattern matching and fixpoints. To handle terms that use these features, DEVOID includes a Preprocess command that translates these terms into equivalent eliminator applications. This command can preprocess a definition (like zip from Section 2) or an entire module (like List, as shown in ListToVect.v) for lifting. It currently supports fixpoints that are structurally recursive on only immediate substructures. To translate such a fixpoint, it first extracts a motive, then generates each case by partially reducing the function’s body under a hypothetical context for the constructor arguments. This is enough to preprocess List; Section 8 discusses possible extensions.

Non-Primitive Projections. By default, projections in Coq are non-primitive. That is, this:

\[ \forall (T : Type) \langle v : \Sigma (n : nat).vector T n \rangle, v = \exists (\pi_v v) (\pi_v v). \]
cannot be proven by reflexivity alone (see Projections.v). Therefore, DEVOID must pack terms like \( v \) into existentials; otherwise, lifting will sometimes fail. This is why the type of `zip_with_is_zipV_p` in the example from Section 2 packs \( v_1 \) and \( v_2 \). For the sake of performance and readability of lifted code, DEVOID is strategic about when it packs.

**Constants.** Because Coq has constants, the implementation of NORMALIZE refolds [3] after normalizing. That is, it acts like the `simpl` tactic in Coq, but with special support for sigma types. For example, to lift the `cons` constructor of a list, after normalizing the promotion of `cons t l`, DEVOID substitutes the projections of the promotion of `l` for their normal forms, which determines and saves the following fact:

\[
\forall \{ T \} \ ( l : \text{list } T), \ \uparrow (\text{cons } t \ l) = \exists \ (S \ (\uparrow_{lB} \ l)) \ (\text{consV} \ (\uparrow_{lB} \ l) \ t \ (\uparrow_{lB} \ l)).
\]

Refolding helps produce more readable lifted code. It also improves lifting performance, since it occurs just once for each constructor.

### 5.2 Optimizing for Efficiency

**Delayed Reduction.** When lifting eliminators, DEVOID computes a list of arguments and delays reduction. It computes this list backwards, storing the new indices that inductive hypotheses refer to as it recurses. This removes the call to `new` in the premise of `Drop-Index`.

**Lazy \( \eta \)-Expansion.** The lifting algorithm assumes that all terms are fully \( \eta \)-expanded. Sometimes, however, \( \eta \)-expansion is not necessary. For efficiency, rather than fully \( \eta \)-expand ahead of time, DEVOID \( \eta \)-expands lazily, only when it is necessary for correctness.

**Caching.** To prevent extra recursion, DEVOID caches the outputs of search, as well as lifted constants, inductive types, and constructors. Since these are constants, lookup is low-cost.

### 5.3 Improving Usability

**Correctness Proofs.** DEVOID has options (used in Example.v) that tell search to generate proofs that its outputs are correct, thereby increasing confidence in and usefulness of those outputs. The proof of coherence is reflexivity. The intuition behind the automation to prove section and retraction (equivalence.ml) is that promote and forget map along corresponding constructors, so inductive cases preserve equalities. Thus, each inductive case of these proofs is generated by a fold that rewrites each recursive reference, with reflexivity as identity.

**Unpacking.** DEVOID includes an `Unpack` command (used in Example.v) that unpacks packed types in functions and proofs. This way, users may access unpacked terms without writing boilerplate code. For simple functions, this command packs arguments and projects results. It splits higher-order functions into two functions. For proofs that use equality, it applies one lemma convert to dependent equality, and one lemma to deal with non-primitive projections.

**User-Friendly Types.** Example.v describes how the user can recover user-friendly types after unpacking. For example, to recover a function with an output of type `vector T n`, the user lifts a proof that the length of the output of the unlifted `list` version of that function is `n`, then rewrites by that lifted proof. The intuition behind this is that this equivalence holds:

\[
\{ \ l : \text{list } T \ & \text{length } l = n \} \simeq \text{vector } T \ n
\]
Recovering a user-friendly type for a proof relating these functions is more complex, since it necessitates reasoning at some point about equalities between equalities. For some index types like `nat`, this follows simply from the fact that the type forms an h-set \([32]\): all proofs of equality between the same two terms of that type are equal. There is preliminary work on determining a general methodology for deriving user-friendly types for proofs that does not rely on any properties of the index type. The idea is to use the adjunction condition along with the proof of coherence by reflexivity; see GitHub issue \#39 for the status of this work.

6 Case Study

We used DEVOID to automatically discover and lift along ornaments for two scenarios:

1. Single Iteration: from binary trees to sized binary trees
2. Multiple Iterations: from binary trees to binary search trees to AVL trees

For comparison, we also used the ornaments that DEVOID discovered to lift functions and proofs using Equivalences for Free! \([30]\) (EFF), a more general framework for lifting across equivalences. DEVOID produced faster functions and smaller terms, especially when composing multiple iterations of lifting. In addition, DEVOID imposed little burden on the user, and the ornaments DEVOID discovered proved useful to EFF.

We chose EFF for comparison because DEVOID is the only tool for ornaments in Coq, and because doing so demonstrates the benefits of specialized automation for ornaments. DEVOID can handle only a small class of equivalences compared to EFF, and it can currently handle only incremental changes to types (one new index at a time). Our experiences suggest that it is possible to use both tools in concert. Section 7 discusses EFF in more detail.

Setup. The case study code is in the `eval` folder of the repository. For each scenario, we ran DEVOID to search for an ornament, and then lifted functions and proofs along that ornament using both DEVOID and EFF. We noted the amount of user interaction (Section 6.1), as well as the performance of lifted terms (Section 6.2). To test the performance of lifted terms, we tested runtime by taking the median of ten runs using `Time Eval vm_compute` with test values in Coq 8.8.0, and we tested size by normalizing and running `coqwc` on the result.\(^2\)

In the first scenario, we lifted traversal functions along with proofs that their outputs are permutations of each other from binary trees (`tree`) to sized binary trees (`Sized.tree`). In the second scenario, we lifted the traversal functions to AVL trees (`avl`) through four intermediate types (one for each new index), and we lifted a search function from BSTs (`bst`) to AVL trees through one intermediate type. Both scenarios considered only full binary trees.

To fit `bst` and `avl` into algebraic ornaments for DEVOID, we used boolean indices to track invariants. While the resulting types are not the most natural definitions, this scenario demonstrates that it is possible to express interesting changes to structured types as algebraic ornaments, and that lifting across these types in DEVOID produces efficient functions.

6.1 User Experience

For each intermediate type in each scenario, we used DEVOID to discover the components of the equivalence. These components were enough for DEVOID to lift functions and proofs with no additional proof burden and no additional axioms. To use EFF, we also had to prove

\(^2\) i5-5300U, at 2.30GHz, 16 GB RAM
that these components form an equivalence; we set the appropriate option to generate these proofs using \textsc{Devoid}. In addition, to use \textsc{EFF}, we had to prove univalent parametricity of each inductive type; these proofs were small, but required specialized knowledge. To lift the proof of the theorem \texttt{pre_permutes} using \textsc{EFF}, we had to prove the univalent parametric relation between the unlifted and lifted versions of the functions that the theorem referenced; this pulled in the functional extensionality axiom, which was not necessary using \textsc{Devoid}.

In the second scenario, to simulate the incremental workflow \textsc{Devoid} requires, we lifted to each intermediate type, then unpacked the result. For example, the ornament from \texttt{bst} to \texttt{avl} passed through an intermediate type; we lifted \texttt{search} to this type first, unpacked the result, and then repeated this process. In this scenario, using \textsc{EFF} differently could have saved some work relative to \textsc{Devoid}, since with \textsc{EFF}, it is possible to skip the intermediate type;\footnote{The performances of the terms that \textsc{EFF} produces are sensitive to the equivalence used; for a 100 node tree, this alternate workflow produced a search function which is hundreds of times slower than the functions that \textsc{Devoid} produced. In addition, the lifted proof of \texttt{pre_permutes} using \textsc{EFF} failed to normalize with a timeout of one hour.} \textsc{Devoid} is best fit where an incremental workflow is desirable.

\section{Performance}

Relative to \textsc{EFF}, \textsc{Devoid} produced faster functions. Figure 10 summarizes runtime in the first scenario for \texttt{preorder}, and Figure 11 summarizes runtime in the second scenario for \texttt{preorder} and \texttt{search}. The \texttt{inorder} and \texttt{postorder} functions performed similarly to \texttt{preorder}. The functions \textsc{Devoid} produced imposed modest overhead for smaller inputs, but were tens to hundreds of times faster than the functions that \textsc{EFF} produced for larger inputs. This performance gap was more pronounced over multiple iterations of lifting.

\textsc{Devoid} also produced smaller terms: in the first scenario, 13 vs. 25 LOC for \texttt{preorder}, 12 vs. 24 LOC for \texttt{inorder}, and 17 vs. 29 LOC for \texttt{postorder}; and in the second scenario, 21 vs. 120 LOC for \texttt{preorder}, 20 vs. 119 LOC for \texttt{inorder}, 24 vs. 125 LOC for \texttt{postorder}, and 31 vs. 52 LOC for \texttt{search}. In the first scenario, the lifted proof of \texttt{pre_permutes} using \textsc{Devoid} was 85 LOC; the lifted proof of \texttt{pre_permutes} using \textsc{EFF} was 1463184 LOC.

We suspect \textsc{Devoid} provided these performance benefits because it directly lifted induction.

\hline
\textsc{EFF} & 1.0 & 5.0 & 67.0 \(33.50x\) & 1062.0 \(354.00x\) & 15370.5 \(530.02x\) \\
\hline
\end{tabular}
\caption{Median runtime (ms) of unlifted (\texttt{tree}) and lifted (\texttt{avl}) \texttt{preorder}, plus unlifted (\texttt{bst}) and lifted (\texttt{avl}) \texttt{search}, over ten runs with inputs ranging from about 10 to about 100000 nodes.}
principles, whereas EFF produced lifted functions in terms of unlifted functions. The multiple iteration case in particular highlights this, since EFF’s approach makes lifted terms much slower and larger as the number of iterations increases, while Devoid’s approach does not.

7 Related Work

Ornaments. Devoid automates discovery of and lifting across algebraic ornaments in a higher-order dependently typed language. In the decade since the discovery of ornaments [23], there have been a number of formalizations and embedded implementations of ornaments [10, 19, 11, 20, 9]. Devoid is the first tool for ornamentation to operate over a non-embedded dependently typed language. It essentially moves the automation-heavy approach of Ornamentation in ML [33], which operates on non-embedded ML code, into the type theory that forms the basis of theorem provers like Coq. In doing so, it takes advantage of the properties of algebraic ornaments [23]. It also introduces the first search algorithm to identify ornaments, which in the past was identified as a “gap” in the literature [20].

Lifting Proofs. Devoid identifies and lifts proofs along a specific equivalence similar to that from existing ornaments work [20]. The need to automatically lift functions and proofs across equivalences and other relations is a long-standing challenge for proof engineers [22, 1, 21, 16, 34, 6]. The univalence axiom from Homotopy Type Theory [32] enables transparent transport of proofs; cubical type theory [5] gives univalence a constructive interpretation.

Our work is closely related to Equivalences for Free! [30], which brings this full circle, using mathematical properties of univalence to enable lifting across equivalences in a substantial subset of CICω without relying on the univalence axiom. In doing so, it introduces and formalizes the relation that our specification depends upon, and implements a framework for lifting in Coq. This framework is more general than Devoid: It lifts along any equivalence, not just ornamental promotions, and can handle opaque terms, with the caveat that users must prove each equivalence themselves; Devoid requires non-opaque terms and lifts along the class of equivalences that correspond to ornamental promotions, taking advantage of the mathematical properties of ornaments to eliminate the need for explicit applications of section and retraction, and to discover and prove certain equivalences automatically. These mathematical properties allow us to automatically lift the induction principle and eliminate references to old terms, which is beneficial for performance.

Similarly, our work is related to CoqEAL [6], which transfers functions along arbitrary relations between types. As these relations do not necessarily need to be equivalences, this framework is more general than our work. Similar tradeoffs between automation and generality apply: CoqEAL produces functions that refer to the old type, and does not yet support automatic inference of relations. In addition, CoqEAL currently only supports automatic transfer of functions, and does not yet handle proofs.

These tools may provide an alternative backend for Devoid. Furthermore, our search algorithm may help discover relations that make these tools easier to use, and our lifting algorithm may help improve automation and efficiency for certain relations in these tools.

Program and Proof Reuse. The problem that we solve is fundamentally about proof reuse, which applies software reuse principles to ITPs. There is a wealth of work in proof reuse, from tactic languages [15] and logical frameworks [4], to tools for proof abstraction and generalization [26, 18], to domain-specific methodologies [12] and frameworks [13].
Devoid focuses on the specific problem of reuse when adding fully-determined indices to types. Other approaches to this problem include combinators which definitionally reduce to desirable terms [14] in the language Cedille, and automatic generation of conversion functions in Ghostbuster [24] for GADTs in Haskell. Our work focuses on a type theory different from both of these, in which the properties that allow for such combinators in Cedille are not present, and in which dependent types introduce challenges not present in Haskell.

Devoid is not the first tool to combine search with reuse. Optician [25] synthesizes bidirectional string transformations; a similar approach may help extend tooling to handle transformations for low-level data. Pumpkin Patch [27] searches the difference in proofs for patches that can be used to repair proofs broken by changes; Devoid uses a similar approach to identify functions that form an equivalence. The resulting tools are complementary: Devoid supports the addition of indices and hypotheses, which Pumpkin Patch does not support; Pumpkin Patch supports changes in values, which Devoid does not support.

8 Conclusions & Future Work

We presented Devoid: a tool for searching for and lifting across algebraic ornaments in Coq. Devoid is the first tool to lift across ornaments in a non-embedded dependently typed language, and to automatically infer certain kinds of ornaments from types alone. Our algorithms give efficient transport across equivalences arising from algebraic ornaments; our case study demonstrates that such automation can make lifted terms smaller and faster as part of an incremental workflow.

Future Work. A future version may support other ornaments beyond algebraic ornaments, with additional user interaction as needed; this may help support, for example, the ornament between \texttt{nat} and \texttt{list}, where \texttt{list} has a new element in the \texttt{cons} case. A future version may loosen restrictions on input types to support adding constructors while preserving inductive structure, recursive references under products, and coinductive types. Integrating with Pumpkin Patch [27] may help remove restrictions Devoid makes about the hypotheses of \texttt{B}. Preprocess currently supports only certain fixpoints; a more general translation may help Devoid support more terms, and discussions with Coq developers suggest that the implementation of such a translation building on work from the equations [28] plugin is in progress. Extending Devoid to generate proofs of coherence conditions for lifted terms may increase user confidence. Proofs that the commands that Devoid implements satisfy their specifications may also increase user confidence. Better automating the recovery of user-friendly types may improve user experience.
